	Eutrophic	86	14/0	43	43	14

\* - denominator – percent of lake with  $\text{PO}_4$  concentration is equal 0

# Climate stimulation ?

(Brohan et al., 2006)

# Conclusions

By 2005 biogeochemical processes in Kola lake ecosystems had altered;  
the symptoms are:

- increase of TOC and share of autochthonous organic matter judging from TOC to Norg ratio
- intensification of nutrients cycle judging from  $\text{NH}_4$  concentration and Norg to  $\text{NH}_4$  ratio as parameters of organic matter destruction
- increasing lake production judging from TP concentration as a parameter of eutrophication

Possible causes of rising lake production:

- climate stimulation
- increase of bioavailable form of nutrients due to intensification of their cycling

If in 1995 and 2000 the restrictive factor of lake production was phosphorus in association with nitrogen, whereas in 2005 that was nitrogen.

**Thanks for your attention**
